

Chess ML

Daniel Cloutier Sagar Patel

December 11, 2020

Abstract

We intend to present an automatic learning method for chess, utilizing deep neural networks. We train our deep neural network using a combination of both methods of neural network training, unsupervised and supervised. Using unsupervised training we allow our engine to pretrain which identify and extract high level features that exist in a high level chess match. The supervised training compares two chess position and evaluates the favorable location between both options. Therefore, we create a deep neural network that requires no prior knowledge regarding the rules of chess and strictly learns from thousands of chess datasets. The resulting deep neural network allows for simulations that extend the possibilities of chess strategies, highly valuable to chess grandmasters and strategist.

1 Introduction

It should have motivation, brief review of others ideas, what is your approach and how this differs from others.

2 Extensive review of other ideas

3 Problem Statement

In this era, there is a massive amount of data collected in a large variety of different topics, of which lots of information can be extracted. The issue here comes with the fact

that we cannot simply extract the information by visual inspection. There is currently too much data.

One such domain that contains a large amount of data is the game of chess. Many players like to study chess games to try and improve their play, but it's very hard to find games that are relevant or interesting to learn from amidst the plethora of games to choose from. Although there are many famous known games such as the Opera game of Paul Morphy vs Duke Karl or game 6 from the 1972 world championship match between Robert Fischer vs Boris Spassky [1], these are usually kept as beginner studies. Also, the fact that they are already well known doesn't necessarily help us discover anything new.

On top of these numerous known games, surely there are many more games that you could learn from. In fact, the website lichess.org logged 68,027,862 games at all levels of play in September of 2020 alone [2]. Some of these could be interesting to study, irrespective of the players ratings not being at the level of Grandmaster. All of this to say, there must be support from algorithms or machine learning techniques to be able to group similar games of interest together, or show games that lie far outside the norm, which could be interesting studies.
